

## The Factorial Composition of the Model Doble Abcx With Fathers and Mathers With a Child With Cognitive Disability

### Abstract

This research was made with the aim of know the factorial composition measures to identify the variables of the model ABCX in Mexican indigenous parents with a child with one cognitive disability, based in the need of recognize the variety and the complexity of this types of families. In this study were used six instruments : Family stress, cohesion adaptability, social support, coherence sense, coping and level of family satisfaction. The results showed that the correlations of each instrument were near to one, the KMO higher than .75 and were found major levels of Bartlett's sphericity, in the scatter plot was observed that the varimax rotation was adequate because it shown orthogonality of the dimensions. To conclude considering the founded measures, these groups of instruments are valid enough to measurement the ABCX model.
